

ABSTRACT

The invention is a rock-climbing device that safely aids climbers during a climb. The rock-climbing device has two carabiners attached to a band which runs through a hollow
5 tube. The climber is able to manually extend the tube over his or her head to an out of reach fixed anchor in the wall of the rock and safely attach the carabiner at the end of the device. This allows the climber to then attach the bottom carabiner of the rock-climbing device to his or her harness. Among other things, the rock-climbing device allows the climber to safely and easily advance up the rock.
